

Minorities Likelier to Get More Low-Value Health Services

June 13, 2017

Does equal access to health services translate to equally good care? Not really, conclude recent findings published in the journal *Health Affairs* that show that Blacks and Hispanics are subjected to less effective and sometimes unnecessary care compared with their white counterparts, reports [YaleNews](#).

For the study, researchers at Yale University examined the prevalence of low-value care services in minority populations. Scientists evaluated common tests and procedures that are medically unnecessary, potentially harmful and economically inefficient. They included 11 different low-value services, such as cardiac testing, vitamin D screening and opioids for treatment of migraines, that Medicare patients received between 2006 and 2011.

Researchers found that minorities received low-value care services at higher rates than white patients and that Black patients received significantly more of five of the 11 services measured (Hispanics received significantly more of six of them). For example, results showed that 17 percent of Blacks and about 13 percent of Hispanics were given inappropriate feeding tubes in comparison to less than 5 percent of white Medicare patients.

“While our descriptive analysis focused on a small, select set of low-value health care services, it highlights the complexity involved in addressing health care disparities in the United States,” said William Schpero, PhD, a student at the Yale School of Public Health and the study’s lead author. “Improving access to care is likely a necessary, but not [a] sufficient part of the policy solution.”

According to researchers, measurements of disparities in those who received high-value, effective care be paired with measurement of disparities in those receiving low-value care in order to prevent minority patients on Medicare from being further exposed to unwarranted medical services.
