mRNA COVID-19 Vaccines are Safe for People with Cancer

The largest peer-reviewed study of the Pfizer-BioNTech COVID vaccine in cancer patients finds no more, and no different, side effects.

February 9, 2022 By National Comprehensive Cancer Network

New research in the February 2022 issue of JNCCN—Journal of the National Comprehensive Cancer Network confirms that mRNA vaccine for COVID-19 are just as safe for people with cancer as they are for cancer-free individuals. Researchers from Fox Chase Cancer Center tracked short-term side-effects from more than 1,753 recipients of the Pfizer BNT162b2 vaccine, and found no additional reactions for patients undergoing active cancer treatment (surgery, chemotherapy, immunotherapy, or radiation therapy) or who had completed treatment.

The results come from in person, phone and online surveys given to people who received two doses of the mRNA vaccine, three weeks apart, between February 16 and May 15, 2021. 1,183 people with a history of cancer responded to both surveys, with 17.8% then currently undergoing treatment. Respondents experienced pain at the injection site, muscle pain, joint pain, fever, chills, headache, nausea, and fatigue at similar rates as those reported by people without cancer from the original clinical trials. Adverse effects for people undergoing immunotherapy also mirrored those in the general population.

“Patients, their families, and their medical caregivers, should absolutely find these results reassuring. We surveyed almost 2,000 patients and found that cancer patients aren’t at risk for any unexpected reactions to being vaccinated compared to people without cancer,” said Eric M. Horwitz, MD, FABS, FASTRO, lead researcher and chair of the Department of Radiation Oncology, Lewis Katz School of Medicine at Temple University. “We now have the data and the clinical experience from thousands and thousands and thousands of cancer patients who have been vaccinated. We know that the mRNA vaccines are safe and are absolutely the most effective way to prevent hospitalization and death from COVID-19.”

“It’s crucial that cancer patients get vaccinated against COVID-19 because we know they can be particularly vulnerable to infection and its consequences, but some people have expressed concerns about possible reactions from the vaccines,” continued Dr. Horwitz. “Before this study, there wasn’t a lot of data specifically on the cancer population so we made sure to collect and report this information to help both patients and physicians make informed decisions to get mRNA vaccines.”

“Getting vaccinated against COVID-19 was an opportunity for me to take control and help protect myself,” said Dan Burkus, who has received treatment from Fox Chase Cancer Center. “Undergoing cancer treatment and follow-up can be terrifying, especially during a pandemic. This new proof that people with cancer won’t have any extra side-effects from the mRNA vaccines is one less thing to worry about and one more reason to get the shot.”

“The investigators convincingly showed no greater incidence of side-effects in patients with a history of cancer, and in fact recipients with a history of cancer had lower rates of pain at the injection site,” commented Natalie Callander, MD, University of Wisconsin Carbone Cancer Center, a member of the NCCN Advisory Committee on COVID-19 Vaccination and Pre-exposure Prophylaxis who was not involved in this research. “Over half the patients in this large prospective study had a history of cancer and about 18% were on active treatment. This study demonstrates that cancer patients experience no greater rate of complications and should help to counteract misinformation about COVID-19 vaccinations. This report provides additional reassurance to practitioners and patients that COVID-19 vaccines are safe and should be offered without hesitation, in accordance with CDC and NCCN recommendations.”
